

# Collision Detection

# Why?

- Realisme
  - Without "quantum effects"
    - Objects pass through other objects
- Game play

# Three Major Parts

- Collision detection
  - Do the objects collide?
- Collision determination
  - Where do they collide?
- Collision response
  - What happens now?

# Phases

- Broad Phase (use placeholder geometry for speed)

- Grids
- Bounding Spheres
- AABB-Algorithm
- OBB-Algorithm
- Subdivisions

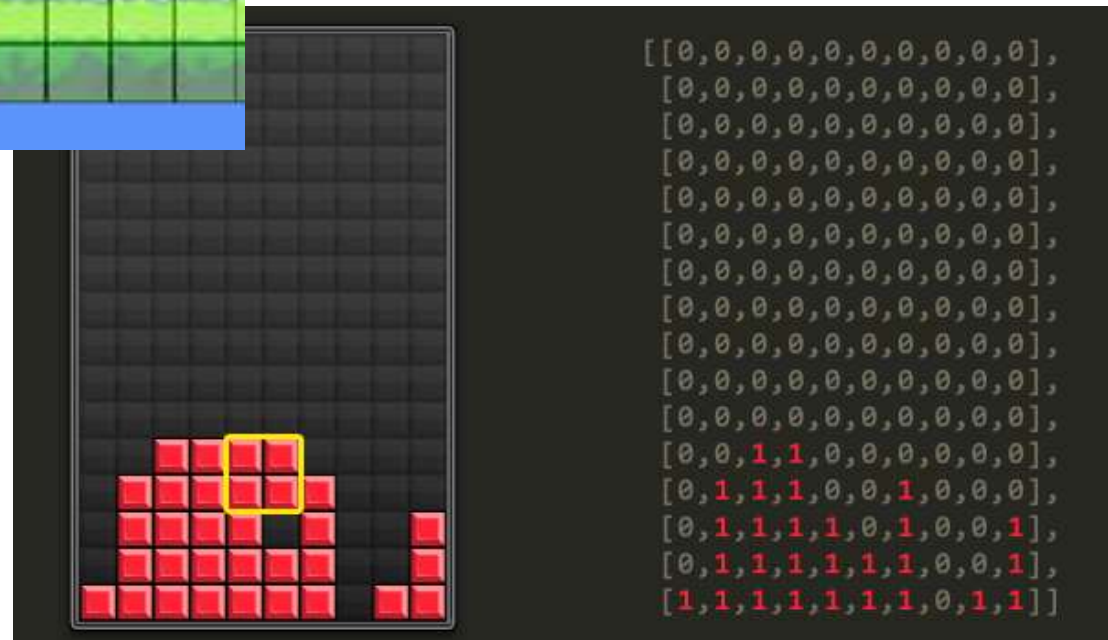

- Narrow Phase (real object is intersected)

- Point-Line
- Point-Triangle
- Triangle-Triangle
- ...

**Broad Phase**

# Regular Subdivision

```

[1,1,1,1,1,1,1,0,1,1,0,0,0,0,0,0]
```

# Regular Subdivision

- Test with regular grid

# Regular Subdivision

# Bounding Spheres

- Collision if  $distance(M_1, M_2)^2 < (r_1 + r_2)^2$

# Calculating Bounding Spheres

- Find the center
  - Average of all vertices
- Find radius
  - For all vertices: calculate max. distance to M
- In mathematics: minimal bounding sphere problem

# Creative Use of Bounding Spheres

# AABB-Algorithm

- Bounding-Spheres:
  - Efficient
  - Inaccurate
- Axis Aligned Bounding Boxes
  - Better Fit
  - Only slightly more complicated

# AABB-Algorithm

# AABB-Algorithm

- No collision if
- $\exists i \in \{x, y, z\} | (A_i^{min} > B_i^{max}) \text{ or } (B_i^{min} > A_i^{max})$ 
  - Separating axis theorem

# AABB - Problems

- While rotating an object, we have to recalculate the bounding box

# Oriented Bounding Box

- Which problems do we have using the AABB approach?
  - *SIGGRAPH 1996, Gottschalk et al.*

# Oriented Bounding Box

- Rotation is no further a problem
- 95% of the situations are solved
- More complicated to calculate than AABB
- Separating axis theorem still works
- More math involved
- Find more information under
  - [www.gamasutra.com](http://www.gamasutra.com)
  - Game Programming Gems (I, II, III)

# k-DOP

- k-Discrete Oriented Polytop
- OBB and AABB are 6-DOPs
- Optimal bounding boxes

# Collision Detection with Rays

- E.x.: car on road, player on terrain
- Test all triangles of all wheels against road geometry
- Often approximation good enough
- Idea: approximate complex object with set of rays

# Another Simplification

- Sometimes 3D can be turned into 2D operations
- Example: maze
- Approximate player by circle
- Test circle against lines of maze

# **Acceleration**

# Handling High Numbers of Objects

- Have to check each object with every other
  - $N \cdot (N-1) \approx N^2$
- Hierarchical irregular subdivision
- Hierarchical Regular subdivision
- Regular subdivision

# Hierarchy Trees

- Bounding Volume Hierarchy = BVH

# Hierarchy Trees

# Quad/Octrees

- Quadtree (2D)

- Octree (3D)

# **Animated Objects**

# Trouble with Animated Objects

# A posteriori (Discrete)

- Advance physics by time step then check for collision
- Simple
  - List of objects  $\rightarrow$  return list of intersections
  - No time variable in calculations
  - Miss actual time of collision
- Need to “fix”

# A priori (Continuous)

- A priori (continuous)
  - Predict future movement
    - Trajectories
  - Can be more precise
  - Can be more stable
  - More complex
    - Dimension of time
    - Often no closed form solution (numerical approach)
    - Aware of how objects move
      - Elastic objects (deforming)

# Animated Objects - Practical Solutions

- Use extruded geometry
- Use oversized geometry
- ...
- Cast ray(s)
- Evaluate often enough
  - Restrict speed
- Extensive testing
- Some cases will be missed

# Independent Render and Game Loop

- Do update in predefined intervals
- Independent from rendering loop
  - Slow rendering does not impact update cycle

**Narrow Phase**

# Narrow Phase

- Many specialized algorithms  
[www.realtimerendering.com/intersections.html](http://www.realtimerendering.com/intersections.html)
- Often not needed
- Will talk about common cases

# Sphere-Box Intersection

- Idea: Coordinate-wise Euclidean distance

```
d = 0
for each i ∈ {x, y, z}
{
    if (Ci < Aimin)
        d = d + (Ci - Aimin)2
    else if (Ci > Aimax)
        d = d + (Ci - Aimax)2
}
if (d > r2)
    return DISJOINT
else
    return OVERLAP
```

# Sphere-Box Intersection

(1) (2)

(3) (4)

3D?
